

Lecture Notes Summary

HTML Lists • Folder Structure • HTML Links

1. HTML Lists

There are **three types** of HTML lists. Ordered lists use numbers, unordered lists use bullet points, definition lists define terminology, and lists can be nested inside one another.

Tag	List Type	Child Elements	Default Marker
<code></code>	Unordered List	<code></code>	Bullet points (•)
<code></code>	Ordered List	<code></code>	Numbers (1. 2. 3.)
<code><dl></code>	Description List	<code><dt></code> , <code><dd></code>	Indented layout

Nested Lists — index.html

This file demonstrates **nesting an ordered list inside an unordered list**. Each `<ul>` item acts as a category heading, and an `<ol type="A">` inside it lists the sub-items with letter labels (A, B, C).

```
<ul>
  <li>Types Of Tense</li>
  <ol type="A">
    <li>Present</li>
    <li>Past</li> <li>Future</li>
  </ol>
</ul>
```

Key point: The `type="A"` attribute on `<ol>` changes the markers to uppercase letters instead of numbers.

Description List — index2.html (commented example)

A `<dl>` pairs a **term** (`<dt>`) with its **definition** (`<dd>`). The code in index2.html was commented out with `<!-- -->`, meaning it won't display in the browser but shows the correct structure:

```
<dl>
  <dt>Title 1</dt>
  <dd>Description text...</dd>
</dl>
```

2. Folder & File Structure

HTML projects use a **hierarchical folder structure**. Folders and files have **parent**, **child**, and **grandchild** relationships:

- **Parent:** A folder that directly contains another folder.
- **Child:** A folder directly inside a parent (e.g. *music* is a child of *examplearts*).

- **Grandchild:** A folder two levels deep (e.g. *dvd* is a grandchild of *examplearts*).

Understanding this structure is essential when writing **relative links** — you must know the file's location relative to the page you are linking from.

3. HTML Links

Links are created with the `<a href="...">` tag. There are three types demonstrated in **index2.html**:

A. Absolute Links

Used to link to **other websites**. The full URL (including *https://*) is required. Adding `target="_blank"` opens the page in a **new tab**.

```
<a href="https://www.facebook.com/" target="_blank">
  Click Here To Open Facebook
</a>
```

B. Relative Links

Used to navigate **within the same project/website**. The path is written relative to the current HTML file's location — no domain needed. **about.html** uses this to link back to the home page:

```
<a href="about.html">Home page</a>
```

Note: The original file used a full Windows path (*D:\Nexskills*...). In real projects, use just the filename or relative path so the site works on any computer.

C. Special Links

Special links use protocol prefixes instead of file paths:

Email link — opens the user's default mail app with the address pre-filled:

```
<a href="mailto:daniyalwarsi808@gmail.com">Email Daniyal</a>
```

Phone link — on mobile devices, tapping this initiates a call:

```
<a href="tel:03362683591">For Contact</a>
```

The About Page — **about.html**

This is a simple page with an `<h1>` heading and a **relative link** back to the home page. It demonstrates how multiple HTML pages link to each other within one project:

```
<h1>This is the about page</h1>
<a href="index2.html">Home page</a>
```
